The Predictive Ability of Clinical Tests for Dry Eye in Contact Lens Wear

Dr. Heiko Pult, Dr. Christine Purslow, Dr. Paul J Murphy

KL-Anpassung

- Ausführliche Anamnese
- Qualifizierte objektive Untersuchung
- Optimale Anpassung der Kontaktlinsen

30% aller Neu-Kontaktlinienträger steigen nach einem Jahr aufgrund Trockenheitsproblemen aus

40-50% aller KL-Träger leiden unter Kontaktlinsen-induziertem trockenen Augen

Probleme

- Prognose der Symptome bei Neu-Linsenträger
 - Optimierte Initial-Versorgung
- Tickende Zeitbomben erfahrener KL-Träger
 - Nachjustierung mittels Neu-Versorgung
- **Kein funktionierenden Test!**

Forschungs-Projekt Zielsetzung:

Die Entwicklung vorhersagewahrscheinlicher Tests zum trockenem Auge beim KL-tragen für uns Praktiker

Dr. Heiko Pult, Dr. Christine Purslow, Dr. Paul J Murphy

Vorgehensweise

1. Überprüfung unseres „Handwerkszeugs“
2. Was zeigen erfahrenen Kontaktlinsenträgern
3. Passt das zur Immunologie des Tränenfilms / aktuellen Grundlagenforschung?
4. Was zeigen Nicht-Kontaktlinsenträgern, also potentiellen KL-Kunden ?
5. Was muss der Anpasser vor der Anpassung sehen um spätere Symptome des trockenen Auges beim KL-Tragen vorhersagen zu können?

Intern. Standard

- randomisiert
- maskiert
- wenn notwendig Kontrollgruppe
- Ermittlung der Menge der Testpersonen mittels Power Kalkulation
- Deklaration of Helsinki
- Publikation in einem peer-reviewed & Medline zitierten Journal,
- etc.

Limbal and Bulbar Hyperaemia in Normal Eyes

Heiko Pult¹, Paul J. Murphy¹, Christine Purslow¹, Jeffrey Nyman² and Russell L. Woods³

¹Cardiff University, School of Optometry and Vision Sciences, Maindy Road, Cathays, Cardiff CF24 4LU, UK, ²Pennsylvania College of Optometry, Philadelphia, PA, USA, and ³Schepens Eye Research Institute, Harvard Medical School, Boston, MA, USA

Abstract

Purpose: To investigate the appearance of limbal and bulbar hyperaemia in normal eyes, their relationship and the inter-observer agreement of clinical grading.

Methods: The right eyes of 120 healthy, non-contact lens-wearing subjects (m = 57, f = 63, median age = 45 years, range 18–77 years) were examined by two trained observers. Limbal and bulbar hyperaemia were scored using the Cornea and Contact Lens Research Unit (CCLRU) redness grading scales interpolated into 0.1 increments. Redness of four quadrants, and overall, were assessed, and quadrant-average redness was calculated. Inter-observer agreement was assessed at the start and end of the study (20 subjects each).

Results: For limbal redness, the overall (1.62 ± 0.46) (mean units \pm S.D.) was not significantly different from the quadrant-average (1.61 ± 0.40) score. For bulbar redness, the overall (2.02 ± 0.49) was higher than the quadrant-average (1.82 ± 0.39) score ($p < 0.0001$). Significant correlations were found between bulbar and limbal quadrants (Pearson: $r \geq 0.43$, $p < 0.0001$). Significant differences in redness were found between quadrants ($p < 0.0001$), with nasal and temporal redder than superior and inferior quadrants. Small effects of age and gender were found for limbal redness. The inter-observer 95% limits of agreement were similar at the start and end of the study. They were larger for overall (0.57) compared with quadrant-average (0.28) redness.

Conclusions: For similar populations, a limbal redness above 2.5 or a bulbar redness above 2.6 (quadrant-average) or 3.0 (overall) may be considered abnormal. Limbal and bulbar redness were correlated. Quadrant-average scores are recommended instead of overall scores, as inter-observer agreement was better.

Clinical Tests for Successful Contact Lens Wear: Relationship and Predictive Potential

Heiko Pult*, Christine Purslow², Monica Berry², and Paul J. Murphy¹

ABSTRACT

Purpose. Although comfort is important for contact lens wearers, common clinical tests can fail to predict patients' symptoms. Lid wiper epitheliopathy (LWE) and lid parallel conjunctival folds (LIPCOP) are related to dry eye symptoms in lens wearers. This study investigates the predictive value of LWF and LIPCOP as objective measures of discomfort, and their relation to the ocular surface in soft contact lens wearers.

Methods. Subjects were classified as symptomatic or asymptomatic, using the Contact Lens Dry Eye Questionnaire (CLDEQ). Pre lens tear break up time (PLBUT), limbal and bulbar hyperaemia, corneal staining, LWE and LIPCOP were assessed in the right eyes of 61 (23 M, 38 F; mean age 42.7 years; range = 18 to 55) experienced contact lens wearers. Differences between groups, and relationships between LWE, LIPCOP (nasal, temporal and sum) and objective signs were examined using non-parametric analyses. The positive and negative predictive values for symptoms of each objective measure were calculated.

Results. Thirty eight subjects were classified as asymptomatic, 23 symptomatic. LWE and LIPCOP severity scores were significantly increased in symptomatic patients (U-test, $p < 0.03$), while no significant differences were found between groups for PLBUT, corneal staining or hyperaemia ($0.29 < p < 0.86$). Significant positive correlations were found between LWE and LIPCOP scores (temporal $r = 0.67$, $p < 0.001$; nasal $r = 0.19$, $p < 0.001$), and between LWE and hyperaemia (bulbar, $r = 0.21$, $p < 0.001$; limbal $r = 0.36$, $p < 0.001$). Age and gender were different in the two groups ($p < 0.05$). The predictive value of temporal LIPCOP was positive = 76.9%, negative = 77.1% with a cutoff value of ≥ 2 (PPV/NPV/cutoff value), of nasal LIPCOP 70.7%/73.0%/ ≥ 1 , of LIPCOP Sum 79.8%/86.5%/ ≥ 2 , and of LWF 53.1%/81.1%/ ≥ 1 .

Conclusions. Contact lens wearers with dryness symptoms exhibit significantly more LWE and LIPCOP, but not increased corneal staining, bulbar hyperaemia or decreased PLBUT. LWF and LIPCOP are significantly correlated; this may reflect their common frictional origin. LIPCOP Sum severity scores appear to be most predictive for symptoms.

Mucins and Ocular Signs in Symptomatic and Asymptomatic Contact Lens Wear

Monica Berry^{*}, Heiko Pult[†], Christine Purslow^{*}, and Paul J. Murphy[§]

ABSTRACT

Purpose. Lid wiper epitheliopathy (LWE) and lid parallel conjunctival folds (LIPCOF) are related to dry eye symptoms in contact lens wearers. Both clinical signs are assumed to be related to mechanical forces during blinking. As the mucus layer is a protector of the ocular surface tissue, this study investigates whether any alterations of mucins are detectable comparing symptomatic and asymptomatic soft contact lens wearers.

Methods. Comfort was evaluated using the Contact Lens Dry Eye Questionnaire. Corneal staining, LWE, and LIPCOF were assessed in the right eyes of 30 (19 men, 31 women; mean age, 32.1 ± 1.4 years) experienced lens wearers. The tear film was sampled using Schirmer strips pressed onto the temporal conjunctiva and from harvested contact lenses. Mucins were assessed in dot-blots and Western blots after electrophoresis on 1% agarose or 4 to 12% NuPAGE Gels. Non-parametric analyses were used to study differences between groups and correlations between objective tests, mucins, and symptoms.

Results. Thirty-one subjects were classified asymptomatic and 19 symptomatic by the questionnaire. LWE and LIPCOF were significantly increased in the symptomatic group ($p < 0.05$). MUC5AC reactivity was significantly decreased in symptomatics ($p = 0.05$). MUC4 was correlated to temporal LIPCOF and LWE, ($r = 0.47$ and -0.46 ; $p < 0.01$). MUC16 and MUC5AC correlated with corneal staining ($0.36 < r < 0.43$; $p < 0.04$).

Conclusions. Symptomatic contact lens wearers exhibit significantly more LWE and LIPCOF, and decreased MUC5AC reactivity. LWE and LIPCOF are significantly correlated; this may reflect their common frictional origin. Increased friction might follow from insufficient mucins, or an altered composition of the resident mucins at the ocular surface. In this study, we show that decreased mucin production is associated with the severity of LWE and LIPCOF.

A Novel Method to Predict the Dry Eye Symptoms in New Contact Lens Wearers

Heiko Pult*, Paul J. Murphy*, and Christine Purslow†

ABSTRACT

Purpose. Lid wiper epitheliopathy (LWE) and lid parallel conjunctival folds (LIPCOF) give moderate prediction levels for dryness symptoms in experienced contact lens (CL) wearers. This study investigated whether a combination of LWE and LIPCOF plus other tear film tests and subjective evaluation before contact lens fitting was better able to predict CL-induced dry eye (CLIDE) symptoms.

Methods. Tear meniscus height, non-invasive break-up time (NIBUT), ocular hyperaemia, LIPCOF, phenol red thread test, corneal and conjunctival staining, and LWE of the right eye of 33 new soft CL wearers (12 males, 21 females, median age = 30.5 years; range = 19 to 44) were assessed in a prospective 2-mo longitudinal study. Symptoms were evaluated by the Ocular Surface Disease Index (OSDI) and subjects were grouped according to their response in the Contact Lens Dry Eye Questionnaire (CLDEQ) during the study (20 symptomatic and 13 asymptomatic). The subjects were fitted with vifilcon A and senofilcon A lenses for a 2-week period, consecutively.

Results. Limbal hyperaemia (repeated measures analysis of variance; $p < 0.05$) and LWE (Friedman; $p < 0.004$) increased significantly during the study but not LIPCOF ($p \geq 0.318$; temporal, nasal, and Sum), bulbar hyperaemia ($p = 0.432$), staining ($p \geq 0.060$), OSDI ($p = 0.126$), or CLDEQ ($p = 0.317$, $\kappa = 0.279$). Limbal hyperaemia significantly decreased in senofilcon A lenses. Wearing comfort among symptomatics was significantly better with senofilcon A ($p = 0.005$). At the enrolment visit, the subjects who became symptomatic exhibited significantly decreased NIBUT and increased LIPCOF and OSDI (range, $p < 0.027$). The best test combination to predict CLIDE (logistic regression analyses) was LIPCOF Sum plus NIBUT and OSDI, (positive predictive value = 87% and accuracy = 91%).

Conclusions. LIPCOF, NIBUT, and OSDI are significant discriminators for CLIDE in new CL wearers compared with hyperaemia, tear meniscus height, phenol red thread test, staining, and LWE. The best test combination is NIBUT plus LIPCOF Sum and OSDI (named the Contact-Lens-Predicting-Test).

Introduction

Lat parallel conjunctival folds (LP) (i.e. LIPCOF Score) (response + nasal LIPCOF, summarized) are reported to be best objective predictor of dry eye symptoms in experienced contact lens wearers¹⁻³. A combination of LIPCOF Score, NIBUT and subjective evaluation has also shown improved predictive ability of later dry eye symptoms in new contact lens wearers⁴.

Aims

To investigate, (i) whether a combination of objective tests and subjective evaluation is able to increase discrimination between symptomatic and asymptomatic experienced contact lens wearers, and (ii) whether this combination improves on the basis of an extended questionnaire response, and (iii) if this combination is able to monitor the contact lens induced dry eye (CLIDE) status.

Methods

Ninety-eight (30M, 68F), mean age 31.8 yrs, range = 18-55) experienced contact lens wearers were classified as CLIDE+ or CLIDE- (n= 40 vs. n= 58), using the Contact Lens Dry Eye Questionnaire (CLDEQ)⁵ (Fig. 1, 2) in a randomized, double masked study.

1. DRYNESS:

How often do you experience dry eyes?
None at all, Rarely, Often

How often do you experience dry eyes?
None at all, Rarely, Often

How often do you experience dry eyes?
None at all, Rarely, Often

How often do you experience dry eyes?
None at all, Rarely, Often

Figure 1: Section of the Contact Lens Dry Eye Questionnaire (CLDEQ).

Consists of 'frequency' and 'severity' of the symptoms.

Consists of '1' to '4' analysis about intensity of the symptoms.

Scoring algorithm for the CLDEQ (sample)

1. Frequency score (0-4) x Severity score (0-4) = Total score (0-16)

2. Total score > 10 = CLIDE+ (Dry Eye)

3. Total score < 10 = CLIDE- (No Dry Eye)

Figure 2: Scoring algorithm of the CLDEQ relating to a dichotomous outcome only (CLIDE+CLIDE-).

Experimental Procedures:

- Pre-test break up time (BUT) by microscope (KowaTM)
- Limbal and better hyperemia (DOLRU Grading Scale, 0-7 increments)
- LIPCOF (table 1)
- Conj. & Corneal staining (Flu. & Rose Bengal gr., ODART Grading Scale, 0-7 increments)
- Lid wiper epitheliopathy (LWE) (Flu. & Rose Bengal gr., in width & height)

Figure 3: LIPCOF degree 2

Figure 4: LIPCOF Area of observation

	LIPCOF degree
No conjunctival folds or atypical micro-folds in one line	0
One permanent and clear parallel fold on one segment and clear parallel fold over elongated individual globe	1
Two permanent and clear parallel folds (normally up to height of 2 zones) or one permanent and clear parallel fold plus some elongated white folds	2
More than two permanent and clear parallel folds (normally higher than 2 zones) or more than two permanent and clear parallel folds plus elongated micro-folds above	3

Table 1: Optimized grading scale of LIPCOF

Statistical analyses:

Differences between groups and predictive ability were examined using receiver operating characteristic curves (ROC). The best test combination to discriminate between CLIDE+ and CLIDE- was evaluated using logistic regression analyses and ROC. The last 37 subjects were observed twice (after 4 weeks) to assess repeatability of resulting combination by 50% limit of agreement and U-test. Mann-Whitney Determined power of completed studies: mean exp./repeatability study: 1.0 / 1.0

Results

Figure 5: LIPCOF Score (response + nasal LIPCOF, summarized) showed best discrimination between CLIDE+ and CLIDE-.

Analysed variables	Log. regression modeling	AUC	95% conf. interval	p-value
(CLDEQ) questions: frequency of symptoms	Symptom (freq. 0 vs. 1) - gritiness (freq. 0 vs. 1)	0.80	0.760 - 0.844	<0.001
(CLDEQ) questions: severity of symptoms	Symptom (freq. 0 vs. 1) - gritiness (freq. 0 vs. 1)	0.80	0.740 - 0.900	<0.001
(CLDEQ) questions: frequency of symptoms + severity of symptoms	Symptom (freq. 0 vs. 1) - gritiness (freq. 0 vs. 1)	0.807	0.770 - 0.858	<0.001
(LIPCOF) test and CLIDE	LIPCOF Score + symptom (freq. 0 vs. 1) - gritiness (freq. 0 vs. 1)	0.881	0.870 - 0.890	<0.001

Table 2: Evaluation of the best test combination by logistic regression analyses and area under the ROC (AUC).

Figure 6: Combining 'frequency' of symptoms with difference intensity (severity - morning) improved subjective predictive ability of dry eye status.

Figure 7: The Contact Lens Dry Eye Index (CLIDE) index was not significantly different in repeated observations (U test, Mann-Whitney, p=0.733) and showed a 50% limit of agreement of 5.5.

Conclusions

- A combination of the questions 'dryness' and 'gritiness' plus LIPCOF Score, named here the CLIDE-index, seems to be a promising method to measure and diagnose dry eye status in experienced contact lens wearers.
- This index showed best discrimination of CLIDE+CLIDE-, with acceptable repeatability.
- Any change in score between visits of more than 5.5 units may be considered abnormal.
